A brief evolution of object-oriented languages

- **Machine language** (binary code)

- **Assembly language** (low-level symbolic programming)

- **Simple procedural languages**, e.g. Fortran, Basic, Pascal, C

- **Simple object-based languages** (without inheritance), e.g. early versions of Visual Basic, JavaScript

- **Fancy object-oriented languages** (with inheritance):
  - C++, Java, C#
The Jack programming language

Jack: a simple, object-based, high-level language with a Java-like syntax

Some sample applications written in Jack:

- Pong game
- Space Invaders
- Tetris

Disclaimer

Although Jack is a real programming language, we don’t view it as an end.

Rather, we use Jack as a means for teaching:

- How to build a compiler
- How the compiler and the language interface with the operating system
- How the topmost piece in the software hierarchy fits into the big picture

Jack can be learned (and un-learned) in one hour.
Hello world

```java
/** Hello World program. */ class Main {
    function void main () {
        // Prints some text using the standard library
        do Output.printString("Hello World");
        do Output.println(); // New line
        return;
    }
}
```

Some observations:

- Java-like syntax
- Typical comments format
- Standard library
- Language-specific peculiarities.
Typical programming tasks in Jack

Jack can be used to develop any app that comes to my mind, for example:

- **Procedural programming:** a program that computes \(1 + 2 + \ldots + n\)
- **Object-oriented programming:** a class representing bank accounts
- **Abstract data type representation:** a class representing fractions (like \(2/5\))
- **Data structure representation:** a class representing linked lists
- **Etc.**

We will now discuss the above app examples.

As we do so, we’ll begin to unravel how the magic of a high-level object-based language is delivered by the compiler and by the VM.

These insights will serve us in the next lectures, when we build the Jack compiler.
Procedural programming example

Jack program = a collection of one or more classes

Jack class = a collection of one or more subroutines

Execution order: when we execute a Jack program, Main.main() starts running.

Jack subroutine:
- method
- constructor
- function (static method)
- (the example on the left has functions only, as it is “object-less”)

Standard library: a set of OS services (methods and functions) organized in 8 supplied classes: Math, String, Array, Output, Keyboard, Screen, Memory, Sys (OS API in the book).

```java
class Main {
    /** Sums up 1 + 2 + 3 + ... + n */
    function int sum (int n) {
        var int sum, i;
        let sum = 0;
        let i = 1;
        while (~(i > n)) {
            let sum = sum + i;
            let i = i + 1;
        }
        return sum;
    }

    function void main () {
        var int n;
        let n = Keyboard.readInt("Enter n: ");
        do Output.printString("The result is: ");
        do Output.printInt(sum(n));
        return;
    }
}
```
Object-oriented programming example

The BankAccount class API (method signatures)

```java
/** Represents a bank account.  
   A bank account has an owner, an id, and a balance.  
   The id values start at 0 and increment by 1 each 
   time a new account is created. */

class BankAccount {

    /** Constructs a new bank account with a 0 balance. */
    constructor BankAccount new(String owner)

    /** Deposits the given amount in this account. */
    method void deposit(int amount)

    /** Withdraws the given amount from this account. */
    method void withdraw(int amount)

    /** Prints the data of this account. */
    method void printInfo()

    /** Disposes this account. */
    method void dispose()

}
```

The BankAccount class API (method signatures)

```java
/** Represents a bank account.  
   A bank account has an owner, an id, and a balance.  
   The id values start at 0 and increment by 1 each 
   time a new account is created. */

class BankAccount {

    /** Constructs a new bank account with a 0 balance. */
    constructor BankAccount new(String owner)

    /** Deposits the given amount in this account. */
    method void deposit(int amount)

    /** Withdraws the given amount from this account. */
    method void withdraw(int amount)

    /** Prints the data of this account. */
    method void printInfo()

    /** Disposes this account. */
    method void dispose()

}
```
Object-oriented programming example (continues)

```java
/** Represents a bank account. */
class BankAccount {
  // class-level variable
  static int newAcctId;

  // Private variables (aka fields / properties)
  field int id;
  field String owner;
  field int balance;

  /** Constructs a new bank account */
  constructor BankAccount new (String owner) {
    let id = newAcctId;
    let newAcctId = newAcctId + 1;
    let this.owner = owner;
    let balance = 0;
    return this;
  }

  // More BankAccount methods.
}
```

```java
// Code in any other class: var int x;
var BankAccount b;  
let b = BankAccount.new("joe");

Explain: return this
The constructor returns the RAM base address of the memory block that stores the data of the newly created BankAccount object

Explain: b = BankAccount.new("joe")
Calls the constructor (which creates a new BankAccount object), then stores a pointer to the object's base memory address in variable b

Behind the scene (following compilation):

// b = BankAccount.new("joe")
push "joe"
call BankAccount.new
pop b

Explanation: the VM code calls the constructor; the constructor creates a new object, pushes its base address onto the stack, and returns;

The calling code then pops the base address into a variable that will now point to the new object.
Object-oriented programming example (continues)

```java
class BankAccount {
    static int nAccounts;
    field int id;
    field String owner;
    field int balance;

    // Constructor ... (omitted)

    /** Handles deposits */
    method void deposit (int amount) {
        let balance = balance + amount;
        return;
    }

    /** Handles withdrawls */
    method void withdraw (int amount){
        if (~(amount > balance)) {
            let balance = balance - amount;
        }
        return;
    }

    // More BankAccount methods.
}
```

```java
... var BankAccount b1, b2; ...
... let b1 = BankAccount.new("joe");
let b2 = BankAccount.new("jane");
do b1.deposit(5000);
do b1.withdraw(1000);
...
```

Explain:  

- In Jack, **void methods are invoked using the keyword** **do** (a compilation artifact)

- The object-oriented method invocation style **b1.deposit(5000)** is a fancy way to express the procedural semantics **deposit(b1,5000)**

**Behind the scene** (following compilation):

```
// do b1.deposit(5000)
push b1
push 5000
call BanAccount.deposit
```
**Object-oriented programming example** (continues)

```java
class BankAccount {
    static int nAccounts;
    field int id;
    field String owner;
    field int balance;

    // Constructor ... (omitted)

    /** Prints information about this account. */
    method void printInfo () {
        do Output.printInt(id);
        do Output.printString(owner);
        do Output.printInt(balance);
        return;
    }

    /** Disposes this account. */
    method void dispose () {
        do Memory.deAlloc(this);
        return;
    }

    // More BankAccount methods.
}
```

// Code in any other class:
...
var int x;
var BankAccount b;

let b = BankAccount.new("joe");
// Manipulates b...
do b.printInfo();
do b.dispose();
...

**Explain** `do b.dispose()`

Jack has no garbage collection; The programmer is responsible for explicitly recycling memory resources of objects that are no longer needed.
Abstract data type example

The Fraction class API (method signatures)

```java
/** Represents a fraction data type. 
   A fraction consists of a numerator and a denominator, both int values */
class Fraction {

    /** Constructs a fraction from the given data */
    constructor Fraction new(int numerator, int denominator)

    /** Reduces this fraction, e.g. changes 20/100 to 1/5. */
    method void reduce()

    /** Accessors */
    method int getNumerator()
    method int getDenominator()

    /** Returns the sum of this fraction and the other one */
    method Fraction plus(Fraction other)

    /** Returns the product of this fraction and the other one */
    method Fraction product(Fraction other)

    /** Prints this fraction */
    method void print()

    /** Disposes this fraction */
    method void dispose()
}
```
Abstract data type example (continues)

/** Represents a fraction data type. 
A fraction consists of a numerator and a denominator, both int values */
class Fraction {
  field int numerator, denominator;

  constructor Fraction new (int numerator, int denominator) {
    let this.numerator = numerator;
    let this.denominator = denominator;
    do reduce() // Reduces the new fraction
    return this
  }

  /** Reduces this fraction */
  method void reduce () {
    // Code omitted
  }

  // A static method that computes the greatest common denominator of a and b.
  function int gcd (int a, int b) {
    // Code omitted
  }

  method int getNumerator () {
    return numerator;
  }

  method int getDenominator () {
    return denominator;
  }

  // More Fraction methods follow.

  // Code in any other class:
  ...
  var Fraction a, b;
  let a = Fraction.new(2,5);
  let b = Fraction.new(70,210);
  do b.print() // prints "1/3"
  ...
  // (print method in next slide)
Abstract data type example (continues)

/** Represents a fraction data type. 
   A fraction consists of a numerator and a denominator, both int values */
class Fraction {

    field int numerator, denominator;

    // Constructor and previously defined methods omitted

/** Returns the sum of this fraction the other one */
method Fraction plus (Fraction other) {

    var int sum;
    let sum = (numerator * other.getDenominator()) + 
              (other.getNumerator() * denominator());
    return Fraction.new(sum , denominator * other.getDenominator());
}

// Similar fraction arithmetic methods follow, code omitted.

/** Prints this fraction */
method void print () {

    do Output.printInt(numerator);
    do Output.printString("/");
    do Output.printInt(denominator);
    return
}

} // Code in any other class:
var Fraction a, b, c; let a = Fraction.new(2,3);
let b = Fraction.new(1,5); 
let c = a.plus(b);
do c.print(); // prints "13/15"
Data structure example

/** Represents a sequence of int values, implemented as a linked list. 
The list consists of an atom, which is an int value, 
and a tail, which is either a list or a null value. */
class List {
    field int data;
    field List next;

    /* Creates a new list */
    constructor List new (int car, List cdr) {
        let data = car;
        let next = cdr;
        return this;
    }

    /* Disposes this list by recursively disposing its tail. */
    method void dispose() {
        if ~(next = null) {
            do next.dispose();
        }
        do Memory.deAlloc(this);
        return;
    }
} // class List.

// Code in any other class:
...
// Creates a list holding the numbers 2,3, and 5:
var List v;
let v = List.new(5, null);
let v = List.new(2, List.new(3, v));
...

### Jack syntax (continues)

| Constants      | Integer constants must be positive and in standard decimal notation, e.g., 1984. Negative integers like $-13$ are not constants but rather expressions consisting of a unary minus operator applied to an integer constant. |
|               | String constants are enclosed within two quote (""") characters and may contain any characters except `newLine` or `doubleQuote`. (These characters are supplied by the functions `String.newLine()` and `String.doubleQuote()` from the standard library.) |
|               | Boolean constants can be true or false. |
|               | The constant null signifies a null reference. |

| Identifiers    | Identifiers are composed from arbitrarily long sequences of letters (a–z, A–Z), digits (0–9), and “_”. The first character must be a letter or “_”. |
|               | The language is case sensitive. Thus x and X are treated as different identifiers. |
Jack data types

**Primitive types** (Part of the language; Realized by the compiler):

- int 16-bit 2's complement (from -32768 to 32767)
- boolean 0 and -1, standing for true and false
- char unicode character (‘a’, ‘x’, ‘+’, ‘%’, ...)

**Abstract data types** (Standard language extensions; Realized by the OS / standard library):

- String
- Array
  
  ... (extensible)

**Application-specific types** (User-defined; Realized by user applications):

- BankAccount
- Fraction
- List
- Bat / Ball
  
  ...(as needed)
## Jack variable kinds and scope

<table>
<thead>
<tr>
<th>Variable kind</th>
<th>Definition / Description</th>
<th>Declared in</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static variables</td>
<td><code>static type name1, name2, ... ;</code> Only one copy of each static variable exists, and this copy is shared by all the object instances of the class (like <code>private static variables</code> in Java)</td>
<td>Class declaration.</td>
<td>The class in which they are declared.</td>
</tr>
<tr>
<td>Field variables</td>
<td><code>field type name1, name2, ... ;</code> Every object instance of the class has a private copy of the field variables (like <code>private object variables</code> in Java)</td>
<td>Class declaration.</td>
<td>The class in which they are declared, except for functions.</td>
</tr>
<tr>
<td>Local variables</td>
<td><code>var type name1, name2, ... ;</code> Local variables are allocated on the stack when the subroutine is called and freed when it returns (like <code>local variables</code> in Java)</td>
<td>Subroutine declaration.</td>
<td>The subroutine in which they are declared.</td>
</tr>
<tr>
<td>Parameter variables</td>
<td><code>type name1, name2, ...</code> Used to specify inputs of subroutines, for example: <code>function void drive (Car c, int miles)</code></td>
<td>Appear in parameter lists as part of subroutine declarations.</td>
<td>The subroutine in which they are declared.</td>
</tr>
</tbody>
</table>
A Jack expression is any one of the following:

- A constant
- A variable name in scope (the variable may be static, field, local, or a parameter)
- The keyword this, denoting the current object
- An array element using the syntax `arrayName[expression]`, where `arrayName` is a variable name of type `Array` in scope
- A subroutine call that returns a non-void type
- An expression prefixed by one of the unary operators `–` or `~`:
  - `–expression` (arithmetic negation)
  - `~expression` (logical negation)
- An expression of the form `expression op expression` where `op` is one of the following:
  - `+` - `*` - `/` (integer arithmetic operators)
  - `&` - `|` (boolean and and or operators, bit-wise)
  - `<` - `>` - `=` (comparison operators)
- `( expression )` (an expression within parentheses)
Jack Statements

```plaintext
let varName = expression;
or
let varName[expression] = expression;

if (expression) {
    statements
}
else {
    statements
}

while (expression) {
    statements
}

do function-or-method-call;

return expression;
or
return;
```
Jack subroutine calls

**General syntax:**  
```
subroutineName(arg0, arg1, ...)  
```

where each argument is a valid Jack expression

Parameter passing is *by-value* (primitive types) or *by-reference* (object types)

**Example 1:**
Consider the function (static method):  
```
function int sqrt(int n)  
```

This function can be invoked as follows:

- `sqrt(17)`
- `sqrt(x)`
- `sqrt((b * b) - (4 * a * c))`
- `sqrt(a * sqrt(c - 17) + 3)`

Etc. In all these examples the argument value is computed and passed by-value

**Example 2:**
Consider the method:  
```
method Matrix plus (Matrix other);  
```

If `u` and `v` were variables of type `Matrix`, this method can be invoked using:  
```
u.plus(v)  
```

The `v` variable is passed by-reference, since it refers to an object.
Noteworthy features of the Jack language

- The (cumbersome) `let` keyword, as in `let x = 0;`
- The (cumbersome) `do` keyword, as in `do reduce();`
- No operator priority:
  
  \[ 1 + 2 * 3 \text{ yields } 9, \text{ since expressions are evaluated left-to-right;} \]
  
  To effect the commonly expected result, use \[ 1 + (2 * 3) \]
- Only three primitive data types: `int`, `boolean`, `char`;
  
  In fact, each one of them is treated as a 16-bit value
- No casting; a value of any type can be assigned to a variable of any type
- Array declaration: `Array x;` followed by `x = Array.new();`
- Static methods are called `function`
- Constructor methods are called `constructor`;
  
  Invoking a constructor is done using the syntax `ClassName.new(argsList)`

**Q:** Why did we introduce these features into the Jack language?

**A:** To make the writing of the Jack compiler easy!

Any one of these language features can be modified, with a reasonable amount of work, to make them conform to a more typical Java-like syntax.
A Jack program is a collection of one or more classes, one of which must be named `Main`. The `Main` class must contain at least one method, named `main()`.

### About this spec:

- Every part in this spec can appear 0 or more times.
- The order of the `field`/`static` declarations is arbitrary.
- The order of the subroutine declarations is arbitrary.
- Each `type` is either `int`, `boolean`, `char`, or a class name.

### A Jack program:

- Each class is written in a separate file (compilation unit).
- The `Jack program` is a collection of one or more classes, one of which must be named `Main`.
- The `Main` class must contain at least one method, named `main()`.
Jack standard library aka language extensions aka Jack OS

class Math {

Class String {

Class Array {

class Output {

Class Screen {

class Memory {

Class Keyboard {

Class Sys {

    function void halt():
    
    function void error(int errorCode)

    function void wait(int duration)

}
Perspective

- Jack is an object-based language: no inheritance
- Primitive type system
- Standard library
- Our hidden agenda: gearing up to learn how to develop the ...
  - Compiler (projects 10 and 11)
  - OS (project 12).
